Contents

1 Why Computer Architecture

1.1 Definitions

- *Computer* is a machine that can be programmed to **carry out computation automatically**
- *Architecture* is a **conceiving, planning, and designing structures**
  - CA has purpose only when given SW
- *Software* is a **description of a computation** expressed in a programming language, any data, and documentation
  - Purpose 1: Definining an DS & A
  - Purpose 2: Executing
- *Interpreter* **executes software**
  - Directly executes instructions expressed in a PL
  - **Does NOT rely on "Turtles all the way down"** (interpreter for interpreter for interpreter. . .) approach
- *Compiling* is the process of **traslating** programs written in one **HLL** (High-level language) into a **LLL** that **has a machine interpreter**

1.2 C Compiling Process

// TODO Find a better way to put diagram in Org files

```
source_code -> preprocessor -> preprocessed source code -> compiler -> assembly code ->
```

- Preprocessed Source Code: Does not contain **comments, macros, includes**, etc
- Assembly Code: **Machine specific**

1.3 Mechanical Computers

- Antikythera Mechanism (200B.C): Count Olumpics days
- Charles Babbage (1849)

1.3.1 Disadvantages

- Parts are small, require individual assembly
- Part shape and size determine computational function
- Parts cause waer and accuracy degrades over time
- Algorithm are slow

1.4 Vacuum Tube Computers

- Colossus

1.4.1 Disadvantages

- About the same volume as mechanical computer
- Uses a lot of electrical energy
- Vacuum tubes burn out

1.5 Transistor

- First one built at AT&T Bell Labs
- Used to use germanium crystal, now use silicon
- Futures are graphene or single layer of carbon

1.6 Two Architectures

1.6.1 Harvard Architecture

Separate memories for instructions and data

1.6.2 Von Neumann Architecture

Single memory for instruction and data

2 Representation

2.1 Electrical Representation of Bits

- **V (max) voltage V -** Δ is recognizes as 1
- **0 to 0** $+ \delta$ is recognizes as 0
- **Rising edge** and **falling edge** are ignored

2.2 Bit String

- **Bus: Collection of k wires carrying k-bits**
- **k-bits** on **k-wires**
- k-bits can represent up to 2^k **values**
- *Bit strings are only meaningful when it is paried with a representation*

3 Regular Representations

Unsigned and 2's complement integers are native data types for most modern circuits

3.1 Unsigned integer, base 2, weighted positional

Regular binary number that we think of normally.
$\texttt{001011} = 0 \times 2^5 + 0 \times 2^4 + 1 \times 2^3 + 0 \times 2^2 + 1 \times 2^1 + 1 \times 2^0 = 11$

3.2 Sign Magnitude

UIB2WP but the MSB is the sign (MSP = left most bit).
$\texttt{101011} = -1(0 \times 2^4 + 1 \times 2^3 + 0 \times 2^2 + 1 \times 2^1 + 1 \times 2^0) = -11$

3.2.1 Characteristics of sign magnitude

- There are two zeros (0000 = +0, 1000 = -0)
- Less number can be represented (duh)

3.3 Two's Complement

MSB weight is negative
`101011` $= -(1 \times 2^4) + 1 \times 2^3 + 0 \times 2^2 + 1 \times 2^1 + 1 \times 2^0) = -5$

3.3.1 Characteristics of two's complement

- Only one bit string for zero
- **Invert bit string and add 1 to get the negative**
- **Uses the same circuit as unsigned integer add/subtraction**

4 Casting/Sign Extension

- Unsigned integer: **Add 0 in front**
- 2's complement: **Add MSB in front**

5 Overflow

- Adding two k-bit unsigned integer resulting in (k+1)-bit result
- $A +_k B = (A + B) \bmod k$ prevents it

6 Gray Code

For sensors where bits need to be detected fast, "gray code" where only one bit changes per number is used.

7 ASCII

7.1 History

Baudot Code in 1870 used to represent 2^5 characters with 5 keys.

7.1.1 Design of ASCII

- **Designed for machine, not human**
- Alphabetic order = integer order of chracter codes
- Upper and lower case only differ in **bit 7, the MSB**

7.1.2 Unicode

- Up to 4 bytes per character
- Currently 14.0, supports emoji

8 Order of Bytes in Memory

- *Big Endian*: **MSB comes first** `0x5060` is stored as `0x5060`
- *Lil Endian*: **LSB comes first** `0x5060` is stored as `0x6050`

9 Floating Point Representation (IEEE 754)

`|S| Exponent | mantissa |`

9.1 Exponent

Exponent is a biased integer. The initial range is -127 $<$ e $<$ 127, sign is made implicit by E = e + Bias = e + 127.

9.2 Mantissa

Unless the number is 0, the MSB of the mantissa must be 1 -> No need to store! (**hidden bit**). Instead, **one extra precision bit** is stored in the end.

9.3 Runtime Anomalies

1. *E = 0, Mantissa = 0,*: ±0, depending on the sign bit
2. *E = 0, Mantissa $\neq$ 0, Mantissa MSB = 0*: De-normalized number, gradual underflow
3. *E = 255, Mantissa = 0*: $\pm\infty$; in general, overflow is set to infinity to help people

4. $E = 255$, *Mantissa* $\neq 0$: Not a Number

10 Memory

10.1 Pointing Function

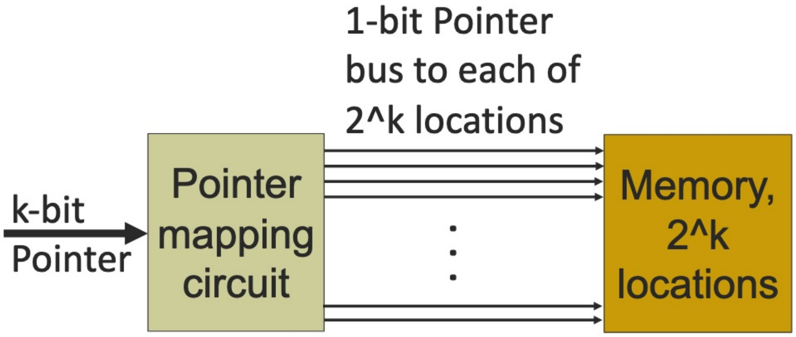

Figure 1: Abstract Pointing Function Diagram

Memory chips are 2D, $2^{k/2} \times 2^{k/2}$ grid creates 2^k intersections -> Only $2*2^{k/2}$ wires needed! Optimized design can reduce number of wires by $\sqrt{2^k}/2$

10.2 Register

k-bit register has k latches to store 2^k bit strings.

11 Pointing

11.1 Decoder

A circuit with n wires input and 2^{n} wires output. Decoding output is selected or not$_{\text{selected}}$

X	Y	D0	D1	D2	D3
0	0	1	0	0	0
1	0	0	1	0	0
0	1	0	0	1	0
1	1	0	0	0	1

2-to-4 decoder truth table. **n inputs and $\mathbf{2^n}$ outputs**.

11.2 Selecting bus

- *Bus*: Group of n wires, carry n bit
- *Multiplexer (mux)*: Selects **from $\mathbf{2^n}$ k-bit input buses, outputs to 1 k-bit output bus**
- *Demultiplexer (Demux)*: Reverse of mux
